# Data types and objects

John Tipton

# Readings

- R for data science
  - Introduction
  - Chapters 10 (Relational data with dplyr), 11 (Strings with stringr), 12 (Factors with forcats), and 13 (Dates and times with lubridate)

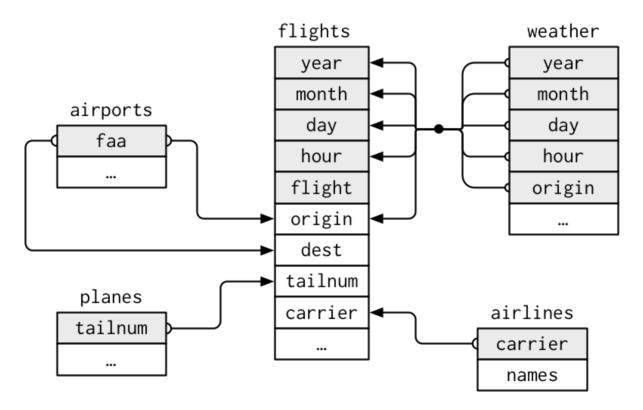

#### Relational data

- Multiple tables of data where the relationships between the data matter
- Common in SQL and other database software
- Common operations include mutating joins, filtering joins, and set operations
- Example: nycflights13 relational data

library(tidyverse)
library(nycflights13)

#### Examine the data

• The data sets include airlines, airports, planes and weather

#### Relational data

- The weather data is connected to flights data by the variables year, month, day, hour, and origin
- The planes data is connected to the flights data by the tailnum variable
- The airports data is connected to the flights data by the faa variable
- The airlines data is connected to the flights data by the carrier variable

#### Relational data

- The variables that connect two or more data tables are called **keys** 
  - o **primary keys** uniquely identifies an observation in its own table
  - o foreign keys uniquely identifies an observation in another table
- A quick check if a variable is a key is to count it

```
planes %>%
  count(tailnum) %>%
  filter(n > 1)

## # A tibble: 0 x 2
## # ... with 2 variables: tailnum <chr>, n <int>
```

• The tailnum variable never shows up more than once in the planes data.

```
airlines %>%
  count(carrier) %>%
  filter(n > 1)
```

## # A tibble: 0 x 2
## # ... with 2 variables: carrier <chr>, n <int>

The carrier variable never shows up more than once in the airlines data

# Question: What is the key for flights?

• There isn't a key

```
flights %>%
  count(flight) %>% ## the flight number gets reused
  filter(n > 1)
```

```
## # A tibble: 3,493 x 2

                                                                260
                                                                          16.1
                                                                                     23.0
                                                                                                     1012
## # ... with 336,766 more rows
```

Weather data appended to the flights\_smaller data

#### Types of joins

- Left join (join the two data sets keeping all variables in the left data set)
- Right join (join the two data sets keeping all variables in the right data set)
- Inner join (join the two data sets keeping all variables that are in both data sets)
  - Typically this is poor as it drops missing values silently
  - Missing values are important to keep track of -- only drop missing values intentionally
- Outer join (join the two data sets keeping all variables that are in either data set)

#### Joins

# Example data

#### Inner Join

```
dat_x %>%
  inner_join(dat_y, by = "key")
## # A tibble: 4 x 3
##
      key x
    <dbl> <chr> <chr>
## 1
        1 x1
               у1
     2 x2
## 2
             y2
     3 x3
## 3
               у3
## 4
     4 x1
               у1
```

- Notice that the variables with keys 5-8 have been dropped
- Half of the data is now missing without any notice!

- Left joins
  - Keeps all of the observations in the "left" dataset

```
dat_x %>%
  left_join(dat_y, by = "key")
## # A tibble: 6 x 3
##
      key x
    <dbl> <chr> <chr>
## 1
        1 x1
               у1
## 2
     2 x2
             y2
     3 x3
## 3
              y3
     4 x1
## 4
               у1
     5 x2
## 5
              <NA>
## 6
     6 x3
             <NA>
```

Notice how all the observations in dat\_x are kept

- Right joins
  - Keeps all of the observations in the "right" dataset

```
dat x %>%
  right_join(dat_y, by = "key")
## # A tibble: 6 x 3
##
      key x
    <dbl> <chr> <chr>
## 1
       1 x1
             у1
## 2
    2 x2 y2
    3 x3 y3
## 3
## 4 4 x1
            y1
## 5 7 <NA> y2
## 6
    8 <NA> y3
```

Notice how all the observations in dat\_y are kept

- Full joins
  - Keeps all of the observations in both datasets

```
dat_x %>%
  full_join(dat_y, by = "key")
## # A tibble: 8 x 3
##
      key x
    <dbl> <chr> <chr>
## 1
       1 x1
              y1
## 2
     2 x2
            y2
     3 x3
## 3
            y3
## 4
     4 x1
            y1
## 5
     5 x2
            <NA>
## 6
     6 x3
             <NA>
    7 <NA> y2
## 7
## 8
     8 <NA> y3
```

Notice how all the observations in dat\_x and dat\_y are kept

## **Duplicate keys**

• Typically, there should not be duplicate keys, but this isn't always true

### Left Joins with duplicate keys

```
dat_x %>%
  left_join(dat_y, by = "key")
## # A tibble: 6 x 3
##
      key x
    <dbl> <chr> <chr>
## 1
    1 x1
              ٧1
    2 x2
            y2
## 2
    3 x3
            у3
## 3
    4 x1
            <NA>
## 4
    1 x2
## 5
             y1
    2 x3
## 6
              y2
```

• Notice that we get all combinations (Cartesian product) of the variables keeping all observations in dat\_x

- Right joins
  - Keeps all of the observations in the "right" dataset

```
dat x %>%
  right_join(dat_y, by = "key")
## # A tibble: 6 x 3
##
      key x
    <dbl> <chr> <chr>
## 1
       1 x1
              y1
## 2
    2 x2
            y2
    3 x3
## 3
            у3
## 4 1 x2
            у1
## 5 2 x3
             y2
    5 <NA> y5
## 6
```

Notice how all the observations in dat\_y are kept

- Full joins
  - Keeps all of the observations in both datasets

```
dat_x %>%
  full_join(dat_y, by = "key")
## # A tibble: 7 x 3
##
      key x
    <dbl> <chr> <chr>
## 1
       1 x1
              у1
## 2
    2 x2
            y2
     3 x3
## 3
            у3
    4 x1
            <NA>
## 4
    1 x2
## 5
            у1
    2 x3
## 6
              y2
## 7
    5 <NA> y5
```

Notice how all the observations in dat\_x and dat\_y are kept

## Defining the key

- Most of the time, the key variable (or variables) are not given the name key
- A natural join uses all of the variables in the two dataframes that are in common

```
flights_reduced <- flights %>%
  select(year:day, hour, origin, dest, tailnum, carrier)
flights_reduced
```

```
## # A tibble: 336,776 x 8
       vear month
                    day hour origin dest tailnum carrier
##
      <int> <int> <int> <dbl> <chr>
##
                                      <chr> <chr>
                                                    <chr>

```

### Joining with keys

- right join flights\_reduced and planes
- Notice the output of the years variables

```
flights reduced %>%
  right_join(planes, by = "tailnum")
## # A tibble: 284,170 x 16
##
      vear.x month
                     day hour origin dest tailnum carrier year.y type
       <int> <int> <int> <dbl> <chr>

#### Filtering joins

- Filter joins drop observations that are missing (typically not used much)
- semi\_join(x, y) keeps all observations in x that have a match in y
  - o Drops all observations in x that don't have a match in y
  - Does not duplicate observations (no Cartesian products)
- anti\_join(x, y) drops all observations in x that have a match in y
  - useful for diagnosing join errors

# Working with joins

- Identifying keys
  - Use your knowledge of the data
  - o Trying to identify keys based on the data values can lead to red herrings

## **Strings**

```
string1 <- "This is a string"
string2 <- 'This is also a string'
string3 <- 'This is a "quoted" string'

string1

## [1] "This is a string"

string2

## [1] "This is also a string"

string3

## [1] "This is a \"quoted\" string"</pre>
```

# Strings - Escape characters

- The escape character for strings is \
- Note: printed strings show the escape characters, not the string

```
print(string3)

## [1] "This is a \"quoted\" string"

• To show the actual string, use writelines

writeLines(string3)
```

## This is a "quoted" string

Other special characters include \n, \t

### Strings

• Join strings into a vector using c()

• String length (number of characters) using str\_length()

```
str_length(c(string1, string2, string3, NA))
```

## [1] 16 21 25 NA

• Join strings together using str\_c()

```
str_c(string1, string2, string3)
```

## [1] "This is a stringThis is also a stringThis is a \"quoted\" string"

• Join strings with a separator character

```
str_c(string1, string2, sep = "\n")
```

## [1] "This is a string $\nThis$  is also a string"

## Strings

- Missing values (NA) are contagious
- The str\_c() function (like most R functions) are vectorized

```
str_c("abc", c("var", NA), "def", sep = "-")
## [1] "abc-var-def" NA
```

• Collapse a vector of strings using collapse

```
str_c(c("abc", "def", "ghi"), collapse = ", ")
## [1] "abc, def, ghi"
```

## Subsetting strings

• Subset strings using str\_sub()

```
beatles <- c("John", "Paul", "Ringo", "George")
# select the 1st through 3rd characters, inclusive
str_sub(beatles, 1, 3)

## [1] "Joh" "Pau" "Rin" "Geo"

# select the last through 3rd from last characters, inclusive
str_sub(beatles, -3, -1)

## [1] "ohn" "aul" "ngo" "rge"</pre>
```

Convert string to lower case

```
str_to_lower(beatles)
## [1] "john" "paul" "ringo" "george"
```

• Can use subsetting in assignment

```
str_sub(beatles, 1, 1) <- str_to_lower(str_sub(beatles, 1, 1))
beatles</pre>
```

## Sting manipulation

```
str_to_lower()
                                               str_sort()
str_to_lower(beatles)
                                             str_sort(beatles)
## [1] "john"
              "paul"
                       "ringo" "george"
                                            ## [1] "george" "john"
                                                                    "paul"
                                                                            "ringo"
                                               • str_order()
  str_to_upper()
str_to_upper(beatles)
                                             str_order(beatles)
## [1] "JOHN"
               "PAUL"
                       "RINGO"
                                "GEORGE"
                                            ## [1] 4 1 2 3
  str_to_title()
str_to_title(beatles)
## [1] "John"
               "Paul"
                       "Ringo"
                                "George"
```

# Strings and searching

• To help troubleshoot string searches, the functions str\_view() and str\_view\_all() are useful

```
costumes <- c("skeleton", "zombie", "witch", "ghoul", "ghost", "ghastly ghoul", "post man
str_view(costumes, "gh")
<div id="htmlwidget-cdfad3d2ae18ba44a2fb" style="width:960px;height:100%;" class="str_view(costumes) clas
```

## Strings and searching

```
str_view(costumes, "e")

<div id="htmlwidget-4719302cfc49e36e874d"
<script type="application/json" data-for=</pre>
```

```
str_view_all(costumes, "e")

<div id="htmlwidget-591897faaf703a86948e"
<script type="application/json" data-for=</pre>
```

• The . character matches any character (except \n)

- How do you search for a .?
  - Remember \ is an escape character
  - To create the regular expression \., you need to escape the escape \
  - ∘ To search for a ., you need the expression \\.

```
dot <- "\\."
writeLines(dot)

## \.

str_view(c("a.c", "d.f", "ghi"), "\\.")

<div id="htmlwidget-2518bcb343dec51dc434" style="width:960px;height:100%;" class="str_viewcolor="black" style="width:960px;height:100%;" style
```

- How do you search for a \?
  - 0 \\\\
- Search at the beginning of a string with ^
- Search at the end of a string with \$

```
str_view(costumes, "^gho")

<div id="htmlwidget-a4c5633f285b69d1b937"
<script type="application/json" data-for=</pre>
```

```
str_view(costumes, "ost$")

<div id="htmlwidget-3c7c5a5c565f74ec00fb"
<script type="application/json" data-for=</pre>
```

Character classes

```
\d - digit
\s - whitespace
\S - non-whitespace
[abc] - matches a, b, or c
[^abc] - matches everything except a, b, or c
```

- Recall: \ is an escape so you need to match \\d or \\s or \\S
- Repetition

```
? - zero or one
+ - one or more
* - zero or more
{n} - exactly n matches
{n, } - n or more matches
{, n} - no more than n matches
{n, m} - between n and m matches
```

- Groupings
  - o (abc) searches for the string "abc

## String detection

• Detect whether a string matches a pattern with str\_detect()

```
str_detect(costumes, "gh")
## [1] FALSE FALSE TRUE TRUE TRUE FALSE
```

• How many words in the stringr library dataset words contain ie after a c?

```
sum(str_detect(words, "cie"))
## [1] 2
```

• What proportion of words in words begin with a ch or a th?

```
mean(str_detect(words, "(^ch)|(^th)"))
## [1] 0.03265306
```

## String detection

• What are some of the words that begin with a ch or a th?

## String detection

• Using str\_detect() within a data.frame to select words starting with "ch" or "th"

```
df <- tibble(word = words, i = seq_along(word))
df %>%
  filter(str_detect(word, "(^ch)|(^th)"))
```

```
## # A tibble: 32 x 2
##

## 4 absolute 4
## 5 accept
## 6 account
## 7 achieve
## 8 across 8
## 9 act
## 10 active
```

## Strings examples

- Use the Trump speech data
- A subset of speeches at Trump rallies

```
file_path <- here::here("data", "Trump_rallies")
all_files <- list.files(file_path, pattern = ".txt")

dat <- list()

for (i in 1:length(all_files)) {
   dat[[i]] <- read_file(paste(file_path, all_files[i], sep = "/"))
}

str_sub(dat[[1]], 1, 200)</pre>
```

## [1] "Thank you. Thank you. Thank you to Vice President Pence. He's a good guy. We've done a grea

# String splitting

• Use str\_split() to split the speech into sentences

```
trump_sentences <- unlist(str_split(dat[[1]], "(\\.\\s)|(\\?\\s)"))
head(trump_sentences)

## [1] "Thank you"

## [3] "Thank you to Vice President Pence" "He's a good guy"

## [5] "We've done a great job together" "And Merry Christmas, Michigan"</pre>
```

• Use the boundary() function to split on line breaks, sentences, words, or characters

```
trump_sentences <- unlist(str_split(dat[[1]], boundary("sentence")))</pre>
```

• View the words in the first three sentences

```
str_view_all(trump_sentences[1:3], boundary("word"))

<div id="htmlwidget-a94f29a6833370d85a35" style="width:960px;height:100%;" class="str_vie"
<script type="application/json" data-for="htmlwidget-a94f29a6833370d85a35">{"x":{"html":"
```

• How many sentences contain "Michigan"?

```
has_michigan <- str_subset(trump_sentences, "Michigan")
michigan_mentions <- str_match(has_michigan, "Michigan")
head(michigan_mentions)</pre>
```

```
## [,1]
## [1,] "Michigan"
## [2,] "Michigan"
## [3,] "Michigan"
## [4,] "Michigan"
## [5,] "Michigan"
## [6,] "Michigan"
```

• How many sentences contain "because", "Thank", or "you"?

```
words_to_find <- c("because", "Thank", "thank", "you")
words_match <- str_c(words_to_find, collapse = "|")
has_words <- str_subset(trump_sentences, words_match)
mentions <- str_match(has_words, words_match)
head(mentions)</pre>
```

```
## [,1]
## [1,] "Thank"
## [2,] "Thank"
## [3,] "Thank"
## [4,] "Thank"
## [5,] "Thank"
## [6,] "you"
```

• Note: this only returns the first match

How to view all the matches?

```
has_words <- str_subset(trump_sentences, words_match)
str_view_all(head(has_words), words_match)</pre>
```

```
<div id="htmlwidget-ae978f7c2cf24e1a5c79" style="width:960px;height:100%;" class="str_victoript type="application/json" data-for="htmlwidget-ae978f7c2cf24e1a5c79">{"x":{"html":"
```

• Extract all matches with str\_match\_all()

```
head(str_match(has_words, words_match))

## [2,] "you"
##
## [[3]]
        [,1]
## [1,] "Thank"
## [2,] "you"
##
```

• Format results in a matrix rather than a list

```
head(str_extract_all(has_words, words_match, simplify = TRUE))

## [,1] [,2] [,3] [,4] [,5] [,6]

## [1,] "Thank" "you" "" "" ""

## [2,] "Thank" "you" "" "" ""

## [3,] "Thank" "you" "" "" ""

## [4,] "Thank" "you" "" "" ""

## [5,] "Thank" "you" "" "" ""

## [6,] "you" "" "" "" ""
```

### Grouped matches

• Define a noun as a word that comes after an "a" or a "the"

```
noun <- "(a|the) ([^]+)"
has_noun <- str_subset(trump_sentences, noun)
head(has_noun)

## [1] "He's a good guy. " "We've done a great job together. "
## [3] "What a victory we had in Michigan. " "What a victory was that. "
## [5] "One of the greats. " "Was that the greatest evening? "</pre>
```

• Doesn't do too great for nouns but seems ok

# **Grouped matches**

• str\_extract() gives complete match, str\_match() gives the individual groups

```
has noun %>%
 str_extract(noun) %>%
   head()
                                         "a victory" "a victory"
                                                                          "the greats."
## [1] "a good"
                        "a great"
## [6] "the greatest"
 has_noun %>%
 str match(noun) %>%
   head()
##
        [,1]
                  [,2] [,3]
## [1,] "a good" "a" "good"
## [2,] "a great" "a" "great"
## [3,] "a victory" "a" "victory"
## [4,] "a victory" "a" "victory"
## [5,] "the greats." "the" "greats."
## [6,] "the greatest" "the" "greatest"
```

# Replacing matches

- Replace matches with str\_replace() (only replace first instance) and str\_replace\_all()
- Replace Trump speeches vowels with "%"

# Replacing matches

• Replace multiple matches with str\_replace\_all()

### Locate strings

• Locate where the strings are with str\_locate() and str\_locate\_all()

•

```
head(str_locate(trump_sentences, "Thank"))
```

```
## [1,] 1 5
## [2,] 1 5
## [3,] 1 5
## [4,] NA NA
## [5,] NA NA
```

#### **Factors**

- A factor is a "qualitative" variable that is encoded with a "numeric" value
- Types of factors
  - o nominal (order doesn't matter) -- colors, religion, etc.
  - ordinal (order matters) -- low/medium/high, young/middle aged/old

```
names <- c("Joe", "Frank", "Prudence", "Cora")
ages <- c("young", "middle aged", "old", "young")
sort(ages)
## [1] "middle aged" "old" "young" "young"</pre>
```

Sorted alphabetically, not by age

much better as a factor

#### **Factors**

• Be careful of typos

```
names <- c("Joe", "Frank", "Prudence", "Cora")
ages <- c("young", "middle aged", "old", "youngs")
sort(ages)
## [1] "middle aged" "old" "young" "youngs"</pre>
```

• Sorted alphabetically, not by age

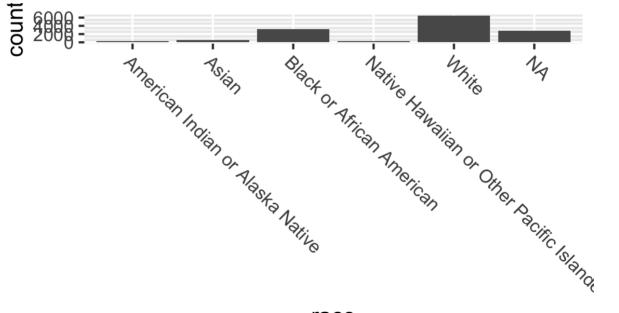

Notice the NA value was created without a warning

## Working with characters

#### Dates and times

- dates and times can be really complicated (lubridate package)
- many different computer formats (POSIXct is really common)

```
library(lubridate)

##
## Attaching package: 'lubridate'

## The following objects are masked from 'package:base':

##
## date, intersect, setdiff, union

today()

## [1] "2021-06-07"

now()

## [1] "2021-06-07 16:30:46 CDT"
```

- How many seconds in a day? In a year?
- What about leap years? Time zones?

# Dates and times

## Dates from strings

• Helpful functions: ymd(), ymd(), myd(), mdy(), dym(), and dmy() for year, month, and day

```
ymd("2020-10-31")

## [1] "2020-10-31"

mdy("October 31st, 2020")

## [1] "2020-10-31"
```

• Can add in time with \_hms() functions

```
# 6 PM on halloween
ymd_h("2020-10-31 18")

## [1] "2020-10-31 18:00:00 UTC"

# Right before midnight
ymd_hms("2020-10-31 11:59:59")

## [1] "2020-10-31 11:59:59 UTC"
```

#### **Dates**

• Process dates with make\_date()

```
dat <- data.frame(
  year = c(2012, 2012, 2013, 2013, 2013, 2014, 2016),
  month = c(5, 6, 11, 4, 1, 10, 9),
  day = c(11, 22, 13, 30, 9, 5, 16),
  hour = c(2, 16, 9, 22, 4, 15, 17)
)</pre>
```

```
dat %>%
  mutate(date = make_date(year, month, day))
```

#### **Dates**

• Process dates with make\_datetime()

```

                                                                          ## 7 2016-09-16 17:37:18 2016-10-01
```

### Time spans

durations

```
# how long since the Big Lebowski was released?
dude_abiding <- today() - ymd("1998-03-06")
dude_abiding

## Time difference of 8494 days

str(dude_abiding)

## 'difftime' num 8494
## - attr(*, "units") = chr "days"

as.duration(dude_abiding)

## [1] "733881600s (~23.26 years)"</pre>
```

#### Time spans

 duration constructors: dseconds(), dminutes(), dhours(), ddays(), dweeks(), and dyears()

```
ddays(3)
## [1] "259200s (~3 days)"

dyears(1)
## [1] "31557600s (~1 years)"
```

• durations can give strange results

```
# Why still in 2016?
ymd_hms("2016-01-01 01:00:00") + dyears(1)

## [1] "2016-12-31 07:00:00 UTC"

# Why did the time change?
ymd_hms("2020-03-08 01:00:00", tz = "America/Chicago") + ddays(1)

## [1] "2020-03-09 02:00:00 CDT"
```

### Time periods

- periods are human-defined terms like weeks and months
- periods can be constructed with: seconds(), minutes(), hours(), days(), weeks(), and years()

```
# Now in 2017
ymd_hms("2016-01-01 01:00:00") + years(1)
## [1] "2017-01-01 01:00:00 UTC"

# Time didn't change
ymd_hms("2020-03-08 01:00:00", tz = "America/Chicago") + days(1)
## [1] "2020-03-09 01:00:00 CDT"
```

#### Intervals

• What should the result of dyears (1) / ddays (365) be?

```
dyears(1) / ddays(365)
## [1] 1.000685
```

• What should the result of years(1) / days(1) be?

```
years(1) / days(1)
## [1] 365.25
```

• Could change based on the year!

```
next_year <- today() + years(1)
  (today() %--% next_year) ## define a date interval

## [1] 2021-06-07 UTC--2022-06-07 UTC

  (today() %--% next_year) / days(1)

## [1] 365

  (today() %--% next_year) / ddays(1)</pre>
```

#### Time zones

- Time zones are really complex
- Time zones are typically tied to cities
- Get your timzone with Sys.timezone()
- Default timezone is UTC
- Get timezones with OlsonNames()

```
head(OlsonNames())

## [1] "Africa/Abidjan" "Africa/Accra" "Africa/Addis_Ababa"

## [4] "Africa/Algiers" "Africa/Asmara" "Africa/Asmera"
```

#### Time zones

```
x <- ymd_hms("2020-10-31 19:00:00", tz = "America/Denver")
y <- ymd_hms("2020-10-31 20:00:00", tz = "America/Chicago")</pre>
z <- ymd_hms("2020-10-31 21:00:00", tz = "America/New_York")
x - y
## Time difference of 0 secs
x - z
## Time difference of 0 secs
times \langle -c(x, y, z)\rangle
times
## [1] "2020-10-31 19:00:00 MDT" "2020-10-31 19:00:00 MDT"
## [3] "2020-10-31 19:00:00 MDT"
with_tz(times, tzone = "America/Los_Angeles")
## [1] "2020-10-31 18:00:00 PDT" "2020-10-31 18:00:00 PDT"
## [3] "2020-10-31 18:00:00 PDT"
```
